

Evolution of Self-Incompatibility

Investigating the role of self-incompatibility systems in the prevention of biparental inbreeding

October 31, 2013

Angiosperms are predominantly hermaphroditic

Self-Fertilization

Self-fertilization

Self-Fertilization

Advantage

Genetic Transmission

Mate Limitation

Self-fertilization

Despite the benefits only 20% of angiosperms are predominately selfing.

Self-fertilization

Despite the benefits only 20% of angiosperms are predominately selfing.

Biparental Inbreeding

- Biparental inbreeding is the mating between close relatives

Biparental Inbreeding

- Biparental inbreeding is the mating between close relatives
- Plant populations are highly susceptible to biparental inbreeding due to local dispersal.

Biparental Inbreeding

- Biparental inbreeding is the mating between close relatives
- Plant populations are highly susceptible to biparental inbreeding due to local dispersal.

Biparental Inbreeding

- Biparental inbreeding is the mating between close relatives
- Plant populations are highly susceptible to biparental inbreeding due to local dispersal.

Biparental Inbreeding

- Biparental inbreeding is the mating between close relatives
- Plant populations are highly susceptible to biparental inbreeding due to local dispersal.

Plants have evolved many systems to avoid self-fertilization

Hermaphroditic

Heterostyly: Spatial separation of male and female parts of the flower

Hercogamy: Temporal separation of male and female maturation

Plants have evolved many systems to avoid self-fertilization

Monoecy

Separate male and female flowers on the same plant

Plants have evolved many systems to avoid self-fertilization

Dioecy

Separate male and female plants

Homomorphic Genetic Self-Incompatibility

- 70% of angiosperms have some form of genetic self-incompatibility

Homomorphic Genetic Self-Incompatibility

- 70% of angiosperms have some form of genetic self-incompatibility
- Genetically similar pollen is rejected based on alleles at the S-locus.

The female and male recognition determinants are tightly linked due to physical proximity and suppressed recombination.

Homomorphic Genetic Self-Incompatibility

- 70% of angiosperms have some form of genetic self-incompatibility
- Genetically similar pollen is rejected based on alleles at the S-locus.
- Self-incompatibility (SI) eliminates self-fertilization and reduces mating between related individuals.

The female and male recognition determinants are tightly linked due to physical proximity and suppressed recombination.

Evolution of Self-incompatibility

- It is generally accepted that SI evolved due to selective pressures to avoid inbreeding.

Evolution of Self-incompatibility

- It is generally accepted that SI evolved due to selective pressures to avoid inbreeding.
- Inbreeding depression is caused by both self-fertilization and biparental inbreeding.

Evolution of Self-incompatibility

- It is generally accepted that SI evolved due to selective pressures to avoid inbreeding.
- Inbreeding depression is caused by both self-fertilization and biparental inbreeding.
- Self-incompatible taxa are very effective at reducing inbreeding due to self-fertilization.

Evolution of Self-incompatibility

- It is generally accepted that SI evolved due to selective pressures to avoid inbreeding.
- Inbreeding depression is caused by both self-fertilization and biparental inbreeding.
- Self-incompatible taxa are very effective at reducing inbreeding due to self-fertilization.
- **Do self-incompatible taxa also benefit from reduced biparental inbreeding?**

Modeling self-incompatible plant populations

- The plant population exists on a geographically continuous surface

Modeling self-incompatible plant populations

- The plant population exists on a geographically continuous surface
- Generations are non-overlapping

$N \times N$ Rectangular Lattice

Hierarchical Equal Area isoLatitude Pixelisation (HEALPix)

Modeling self-incompatible plant populations

- The plant population exists on a geographically continuous surface
- Generations are non-overlapping
- Each cell represents a single individual

$N \times N$ Rectangular Lattice

Hierarchical Equal Area isoLatitude Pixelisation (HEALPix)

- Hermaphroditic

Plants

- Hermaphroditic
- Diploid

Plants

- Hermaphroditic
- Diploid
- Two chromosomes per haploid set ($2n = 4$)

- **No Self-Incompatibility (NSI):**

- All individuals are compatible with themselves and all other individuals. Selfing occurs when pollen does not disperse out of its original cell.

Mating Systems

- **No Self-Incompatibility (NSI):**

- All individuals are compatible with themselves and all other individuals. Selfing occurs when pollen does not disperse out of its original cell.

- **Physical Self-Incompatibility (PSI):**

- Individuals are obligate outcrossers but there is no genetic mating system in place. Selfing is prevented but biparental inbreeding is always allowed.

- **No Self-Incompatibility (NSI):**

- All individuals are compatible with themselves and all other individuals. Selfing occurs when pollen does not disperse out of its original cell.

- **Physical Self-Incompatibility (PSI):**

- Individuals are obligate outcrossers but there is no genetic mating system in place. Selfing is prevented but biparental inbreeding is always allowed.

- **Gametophytic Self-Incompatibility (GSI):**

- The SI phenotype of the pollen is determined by its own gametophytic haploid genotype.

Gametophytic Self-Incompatibility (GSI)

Genetically, the rejection of the pollen is determined by its own gametophytic haploid genotype.

- **No Self-Incompatibility (NSI):**

- All individuals are compatible with themselves and all other individuals. Selfing occurs when pollen does not disperse out of its original cell.

- **Physical Self-Incompatibility (PSI):**

- Individuals are obligate outcrossers but there is no genetic mating system in place. Selfing is prevented but biparental inbreeding is always allowed.

- **Gametophytic Self-Incompatibility (GSI):**

- The SI phenotype of the pollen is determined by its own gametophytic haploid genotype.

- **No Self-Incompatibility (NSI):**

- All individuals are compatible with themselves and all other individuals. Selfing occurs when pollen does not disperse out of its original cell.

- **Physical Self-Incompatibility (PSI):**

- Individuals are obligate outcrossers but there is no genetic mating system in place. Selfing is prevented but biparental inbreeding is always allowed.

- **Gametophytic Self-Incompatibility (GSI):**

- The SI phenotype of the pollen is determined by its own gametophytic haploid genotype.

- **Sporophytic Self-Incompatibility Codominant (SSI):**

- The SI phenotype of the pollen is determined by the diploid genotype of the sporophyte. All S-alleles are co-dominant in the pollen.

- **No Self-Incompatibility (NSI):**

- All individuals are compatible with themselves and all other individuals. Selfing occurs when pollen does not disperse out of its original cell.

- **Physical Self-Incompatibility (PSI):**

- Individuals are obligate outcrossers but there is no genetic mating system in place. Selfing is prevented but biparental inbreeding is always allowed.

- **Gametophytic Self-Incompatibility (GSI):**

- The SI phenotype of the pollen is determined by its own gametophytic haploid genotype.

- **Sporophytic Self-Incompatibility Codominant (SSI):**

- The SI phenotype of the pollen is determined by the diploid genotype of the sporophyte. All S-alleles are co-dominant in the pollen.

- **Sporophytic Self-Incompatibility Dominant (BSI):**

- The SI phenotype of the pollen is determined by the diploid genotype of the sporophyte. Dominance relationships exist between S-alleles in pollen.

Sporophytic Self-Incompatibility (SSI)

Genetically, the rejection of the pollen is determined by the diploid genotype of the sporophyte (the pollen parent plant).

Sporophytic Self-Incompatibility (SSI)

Different dominance relationships exist between alleles in SSI systems.

	Pollen Phenotype
SSI Codominance (SSI)	All alleles are codominant
SSI Dominance (BSI)	Some alleles will be dominant over others

Sporophytic Self-Incompatibility (SSI)

Genetically, the rejection of the pollen is determined by the diploid genotype of the sporophyte (the pollen parent plant).

Simulation

- Each parent plant will generate and disperse pollen

Parent Plant

Simulation

- Each parent plant will generate and disperse pollen
- Pollen will be evaluated for compatibility with the pollen recipient

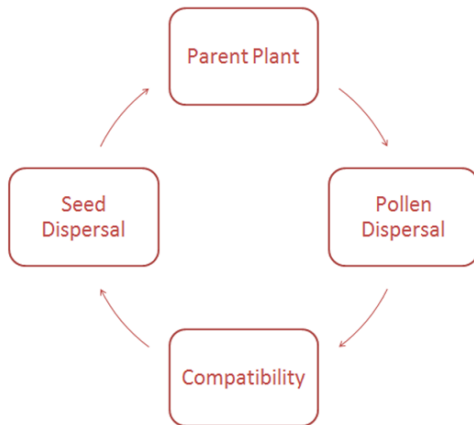

Simulation

- Each parent plant will generate and disperse pollen
- Pollen will be evaluated for compatibility with the pollen recipient
- Fertilized ovules will generate and disperse seeds.

Simulation

- Each parent plant will generate and disperse pollen
- Pollen will be evaluated for compatibility with the pollen recipient
- Fertilized ovules will generate and disperse seeds.
- Seeds will produce plants which replace previous generation.

Analysis: Probability of Identity by Descent

- Probability of identity by decent is a measure of inbreeding.

Analysis: Probability of Identity by Descent

- Probability of identity by decent is a measure of inbreeding.
- Two alleles will be considered identical by descent if they are both identical copies of the same allele in the grandparent generation.

Analysis: Probability of Identity by Descent

- Probability of identity by decent is a measure of inbreeding.
- Two alleles will be considered identical by descent if they are both identical copies of the same allele in the grandparent generation.

Analysis: Probability of Identity by Descent

- Probability of identity by decent is a measure of inbreeding.
- Two alleles will be considered identical by descent if they are both identical copies of the same allele in the grandparent generation.
- The probability of grandparental identity by descent will be determined for each loci under different mating systems.

Analysis: Probability of Identity by Descent

- Probability of identity by decent is a measure of inbreeding.
- Two alleles will be considered identical by descent if they are both identical copies of the same allele in the grandparent generation.
- The probability of grandparental identity by descent will be determined for each loci under different mating systems.

Solid line is the expected level under random mating
Dashed line is the expected level if selfing were prohibited.

Physical Self-Incompatibility

This represents the level of inbreeding when only selfing is prohibited.

Dominant Sporophytic Self-Incompatibility

Least stringent form of SI behaves similarly to PSI.

Gametophytic Self-Incompatibility

Loci linked to S show a large reduction in identity by descent which increases as linkage decreases.

Codominant Sporophytic Self-Incompatibility

Most stringent form of SI. Shows a similar pattern as GSI.

- At unlinked loci, the genetic self-incompatibility systems are only slightly more effective at reducing inbreeding than physical self-incompatibility.

- At unlinked loci, the genetic self-incompatibility systems are only slightly more effective at reducing inbreeding than physical self-incompatibility.
- However, this model did not include inbreeding depression which would provide a selective advantage for avoiding inbreeding.

Modeling Inbreeding Depression

Modeling Inbreeding Depression

A

- Plants who carry a mutation at the A locus and mate with relatives who are also carriers will be penalized.

Modeling Inbreeding Depression

A

- Plants who carry a mutation at the A locus and mate with relatives who are also carriers will be penalized.
- Ovules will abort if they carry two mutated copies of the A locus.

Expected Results

Is biparental inbreeding reduced in self-incompatible plant populations experiencing inbreeding depression?

- If PSI shows similar levels of inbreeding as the genetic forms of SI that will suggest that SI systems do not prevent biparental inbreeding.

Expected Results

Is biparental inbreeding reduced in self-incompatible plant populations experiencing inbreeding depression?

- If PSI shows similar levels of inbreeding as the genetic forms of SI that will suggest that SI systems do not prevent biparental inbreeding.
- A reduction in inbreeding below the level of PSI would indicate that genetic SI reduces biparental inbreeding.

Conclusion

- It is commonly assumed that self-incompatibility systems evolved in response to selective pressures to avoid inbreeding.

Conclusion

- It is commonly assumed that self-incompatibility systems evolved in response to selective pressures to avoid inbreeding.
- Using a population simulation I will theoretically determine if the success of genetic self-incompatibility is mainly due to the prevention of selfing or if it can be extended to the prevention of biparental inbreeding.
